

Behavior-matched openings raise harm with length; wrong-behavior openings do not

Matched $\approx$ mismatched through $N \approx 5$ (a short affirmative nudge is behavior-agnostic); the gap turns on at $N \geq 10$, reaching $+0.92$ at $N=20$ (paired Wilcoxon $p=0.0001$, $n=89$). Both conditions use real harmful-response openings of equal length, cut identically — so the difference isolates the opening's behavior-specific content, not its mere presence.
